## Hardware Specifications:

Model Name:	MacBook Pro
Processor Name:	Intel Core i7
Processor Speed:	3.3 GHz
Number of Processors:	1
Total Number of Cores:	2
L2 Cache (per Core):	256 KB
L3 Cache:	4 MB
Memory:	16 GB

## Browsers Used:

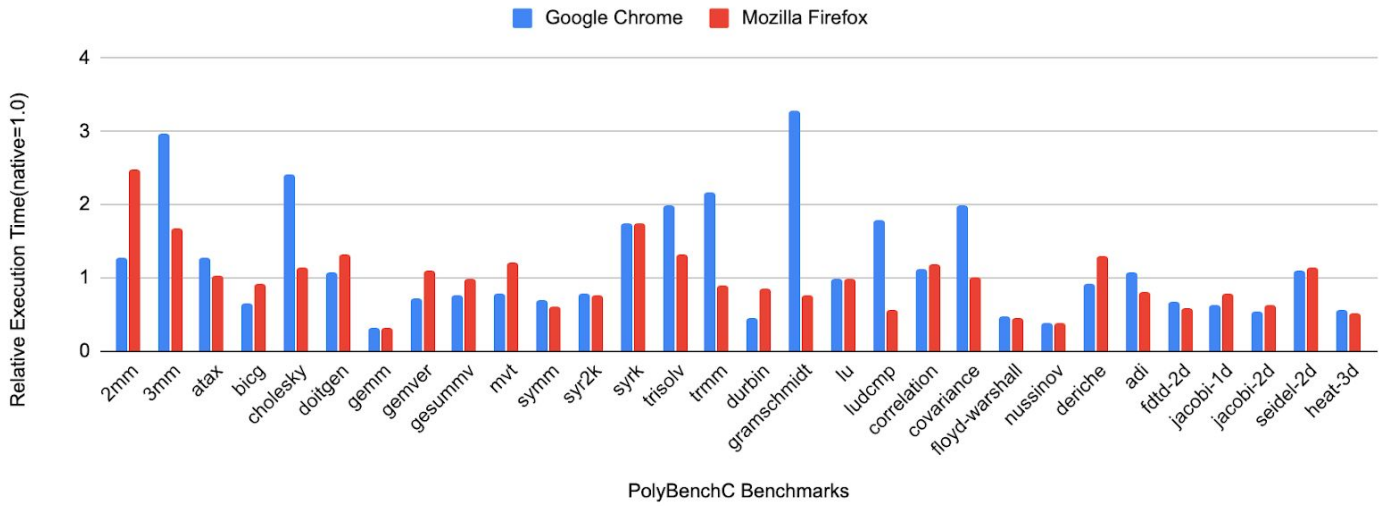

Google Chrome  
Mozilla Firefox

## Scripts written:

Generating executables (both gcc and emcc) with and without timing analysis  
Running and timing native code  
Generating Instruction mix, dynamic instruction count and hot code in wasabi and pin tools

# Experiment 1- Relative Execution Time

Performance of the PolyBenchC on MacBook Pro 2017 - O0 optimisation

Performance of the PolyBenchC on MacBook Pro 2017 - O1 optimisation

Performance of the PolyBenchC on MacBook Pro 2017 - O2 optimisation

Performance of the PolyBenchC on MacBook Pro 2017 - O3 optimisation

From these graphs, we see that Firefox performs better for unoptimized ( -O0 mode). However, Chrome performs consistently better for all 3 stages of optimization.

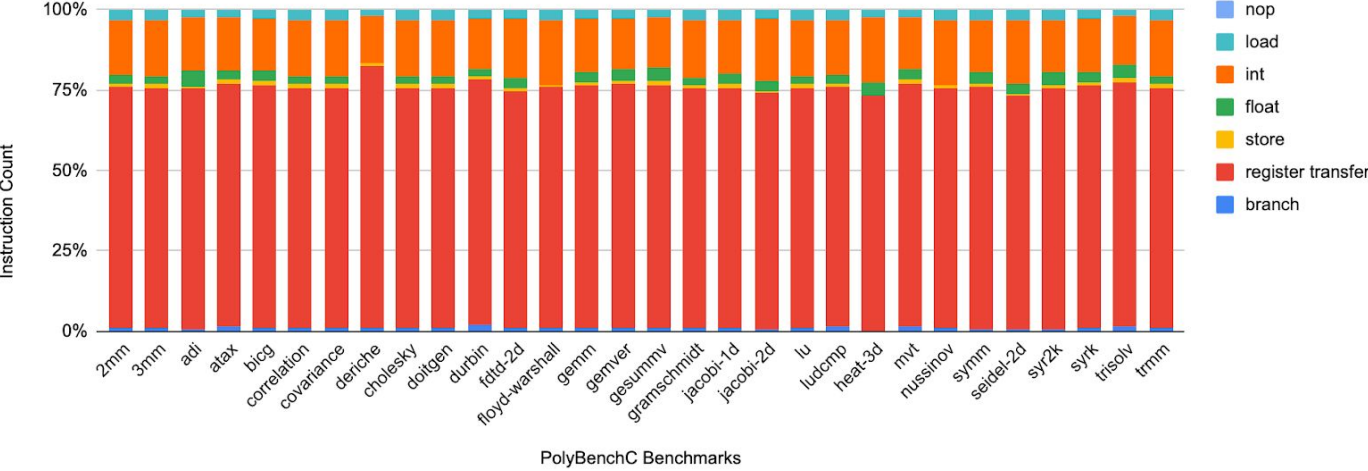

Also, we notice that the unoptimized code is faster through WebAssembly than locally. However, this doesn't hold for optimized code as the gcc/g++ optimization techniques are far better than emcc. Also being a client-side interface further adds to overheads in the optimized stage.

## Experiment 2 - Instruction Mix Analysis

Native O0 optimisation

Wasabi O0 optimisation

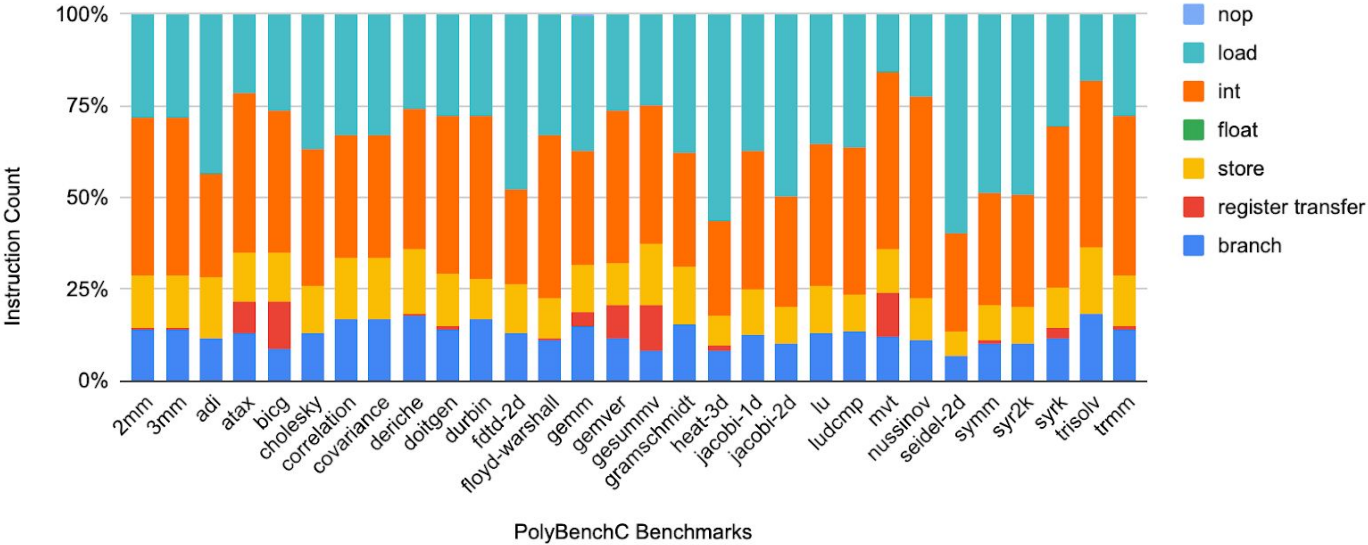

Native O1 Optimisation

Wasabi O1 optimisation

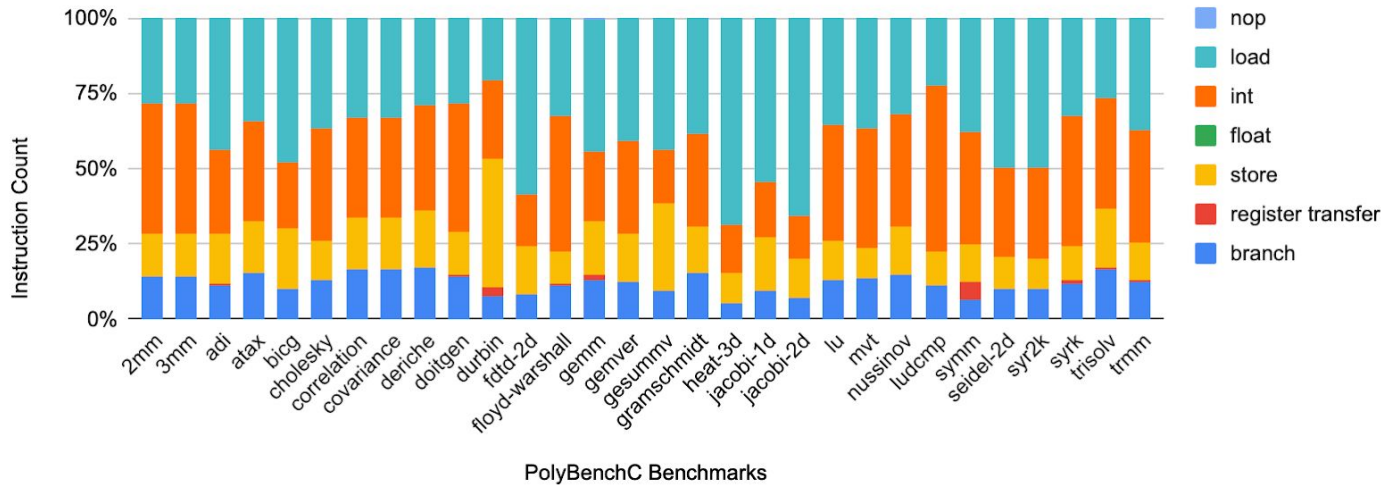

Native O2 Optimisation

Wasabi O2 optimisation

### Native O3 optimisation

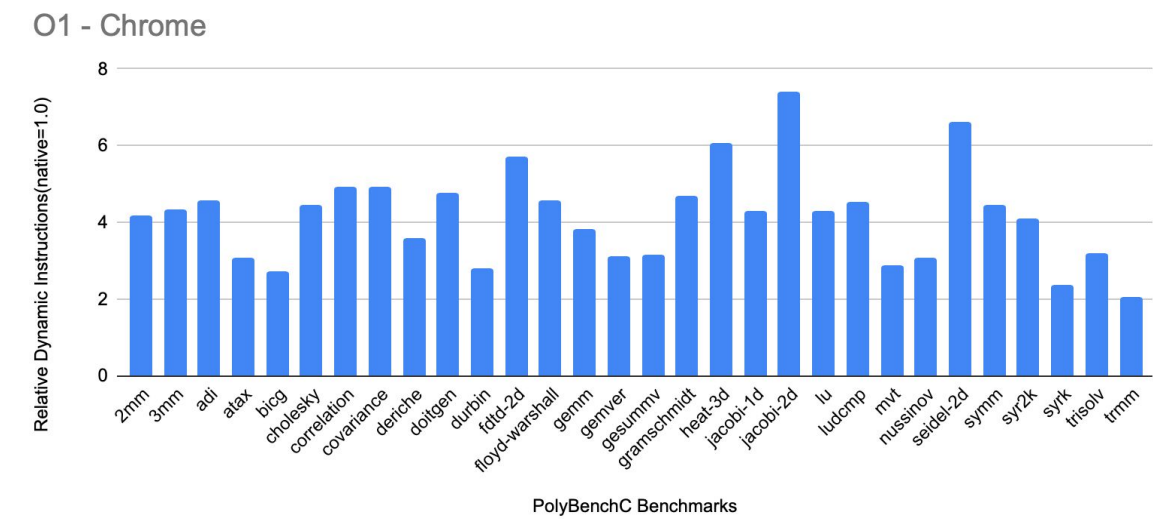

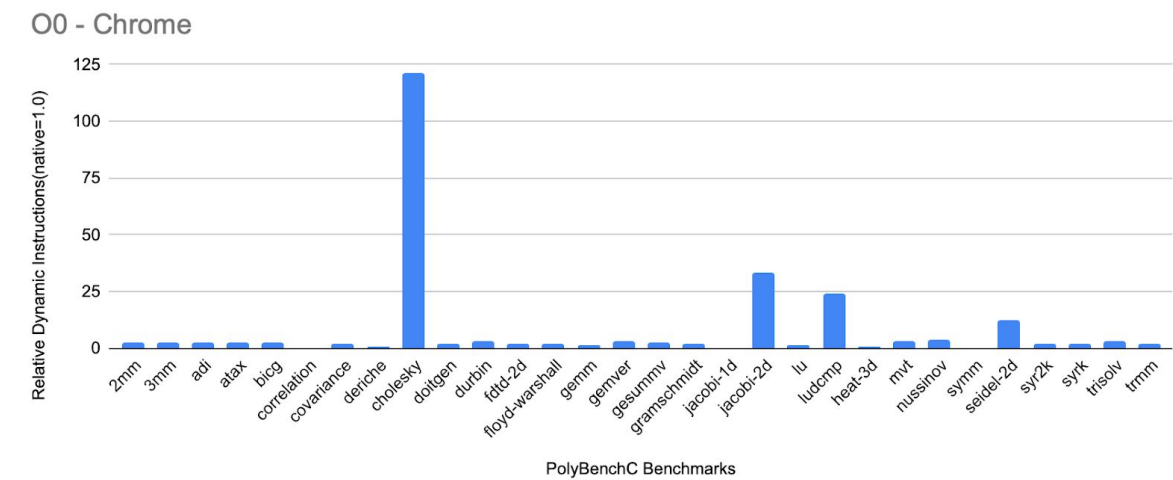

### Wasabi O3 optimisation

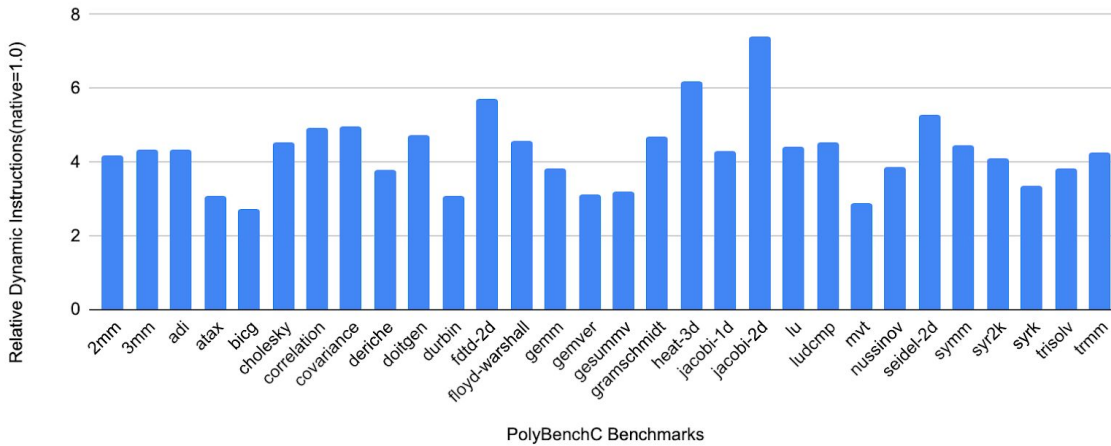

Across all 4 optimization stages, we observe that the native compilers tend to favour load and store instructions whereas the WebAssembly compiler prefers register transfer. Since primarily WA works on the client side, it doesn't have complete access to the storage systems, and hence relies on register transfer for most of its computations. Google Chrome and Firefox, being web browsers, suffer from poor instruction selection, hence resulting in larger code.

# Experiment 3 - Instruction Count

## O2 -Chrome

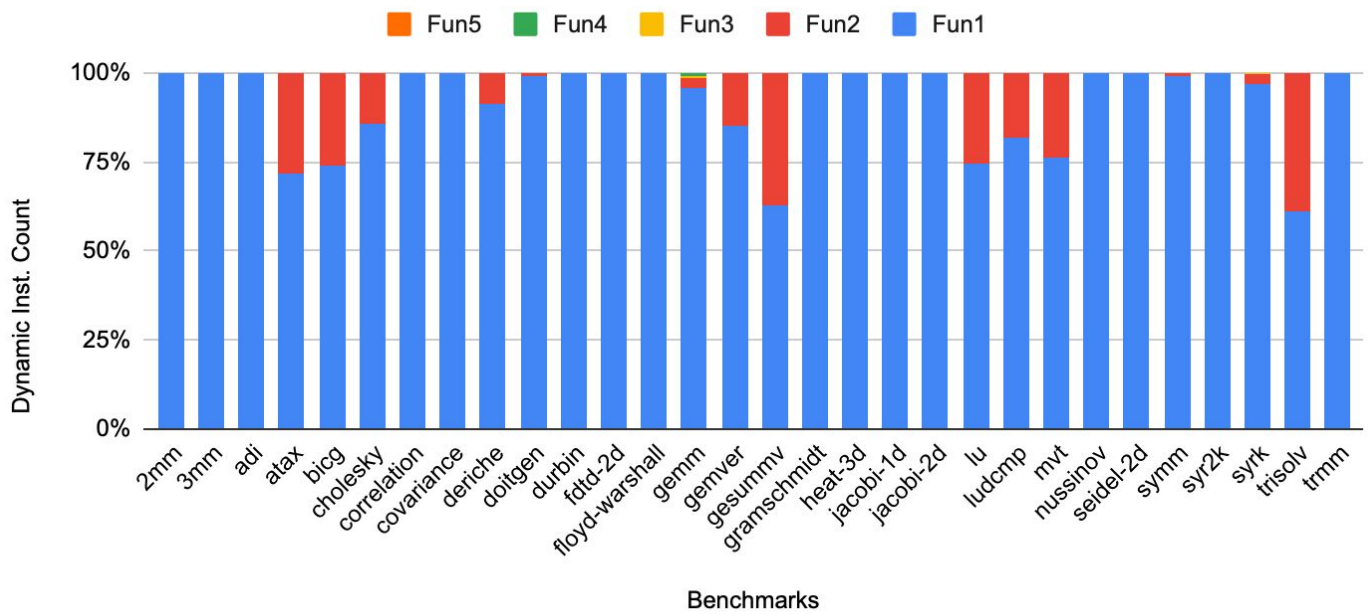

## O3- Chrome

Here, we notice, apart from a few outliers, the instructions are scaled up uniformly in the WebAssembly code as compared to native compilers. Generally by a factor of 5. This is due to the multiple overheads that WA needs to handle due to its virtualization and abstraction from the OS.

## Experiment 4 - Hot Code

### O0 Pintool

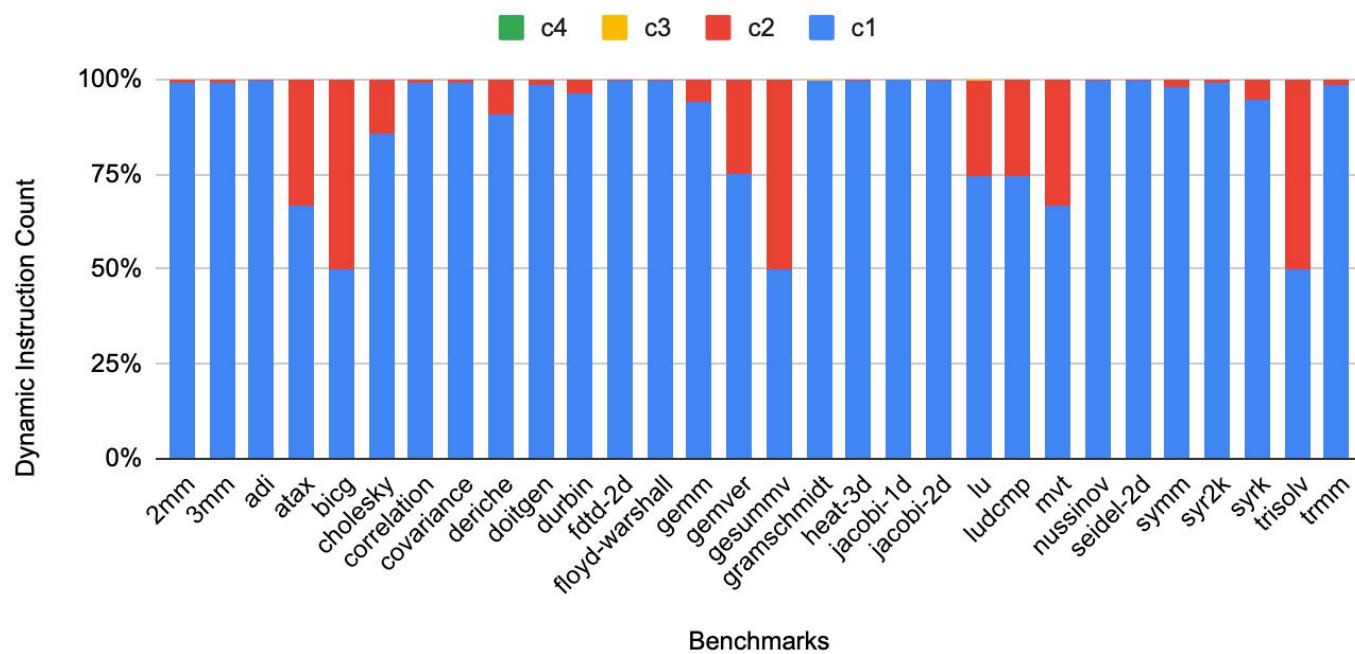

### O0 Wasabi

## O1 Pintool

## O1 Wasabi

## O2 Pintool

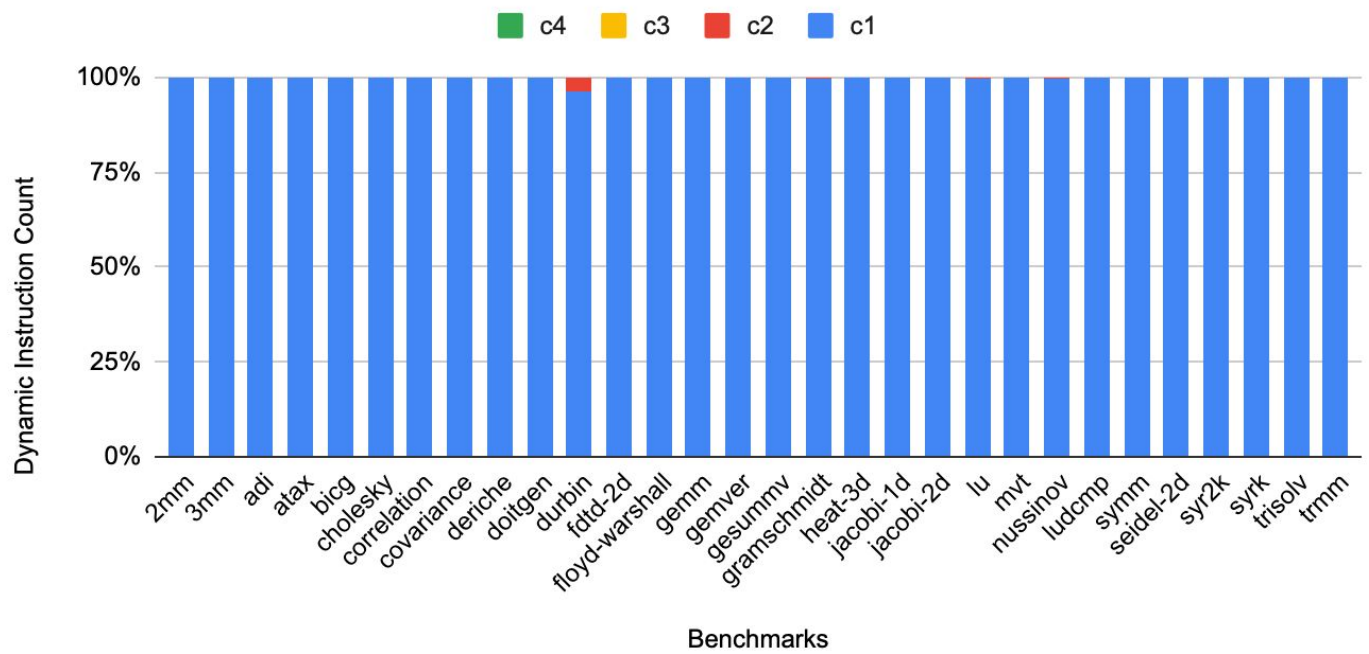

## O2 Wasabi

## O3 Pintool

## O3 Wasabi

Here we notice that for most functions the instructions are concentrated in one function for the native compiler (Generally 90%+ of the instructions mix). However, for the WebAssembly code, there are multiple functions with comparable magnitudes of instructions count that are executed frequently. Again, due to poor code selection in Chrome and Firefox, the dynamic count of function execution increases.

**Note:** *All the data used for preparing the graphs is available in [this](#) sheet*
